

ABSTRACT

The method and system provides for receiving at a local base transceiver station a wireless signal and for routing that signal from the local base transceiver station to a remote base station controller. In exemplary embodiments, control logic stored in local components of a wireless telecommunications network can select one of multiple remote base station controllers to which to route the signal. Further, local telecommunications components can make these selections based on the occurrence of various triggering events, such as the occurrence of a particular time/day/date, or such as the involvement of a particular client station, or the signal having a particular form or content.
